Parameters

What this chapter contains

The chapter describes the parameters, including actual signals, of the control program. At the end of the chapter, on page [568](#), there is a separate list of the parameters whose default values are different between 50 Hz and 60 Hz supply frequency settings.

Terms and abbreviations

Term	Definition
Actual signal	Type of parameter that is the result of a measurement or calculation by the drive, or contains status information. Most actual signals are read-only, but some (especially counter-type actual signals) can be reset.
Def	(In the following table, shown on the same row as the parameter name) The default value of a parameter when used in the Factory macro. For information on other macro-specific parameter values, see chapter Default configuration .

	Damper control	See the figure below.	54
<p>The diagram illustrates the sequence of events for damper control. It features five main signal traces:</p> <ul style="list-style-type: none"> Start/stop command (Group 20 Start/stop/direction): A step function that transitions from low to high at the start of the drive and returns to low at the end. Start interlock signal (parameters 20.41...20.44): A step function that transitions from low to high when the drive starts and returns to low when the drive stops. Damper control relay status (Group 10 Standard DI, RO): A step function that transitions from low to high when the relay is energized and returns to low when it is de-energized. Damper status: A signal that starts at a low level labeled 'Damper closed'. When the drive starts, it ramps up linearly to a high level labeled 'Damper open'. The duration of this ramp is marked as 'Damper opening time'. When the drive stops, it ramps down linearly to a low level labeled 'Damper closed'. The duration of this ramp is marked as 'Damper closing time'. Run permissive signal from the damper end switch when the damper is fully opened. (parameter 20.41): A step function that transitions from low to high when the damper reaches the 'Damper open' state and returns to low when it reaches the 'Damper closed' state. Motor status: A signal that starts at a low level. When the drive starts, it ramps up linearly to a high level. The duration of this ramp is marked as 'Acceleration time (par 23.12)'. When the drive stops, it ramps down linearly to a low level. The duration of this ramp is marked as 'Drive coasts to a stop'. <p>Vertical dashed lines indicate the start and end of the drive cycle. The 'Damper opening time' and 'Damper closing time' are shown as horizontal double-headed arrows below the damper status signal.</p>

15.05	<i>RO/DO force selection</i>	The electrical statuses of the relay/digital outputs can be overridden, for example, for testing purposes. A bit in parameter <i>15.06 RO/DO forced data</i> is provided for each relay or digital output, and its value is applied whenever the corresponding bit in this parameter is 1. Note: Boot and power cycle reset the force selections (parameters <i>15.05</i> and <i>15.06</i>).	0000h

21 Start/stop mode		Start and stop modes; emergency stop mode and signal source selection; DC magnetization settings.	
21.01	<i>Start mode</i>	Selects the motor start function for the vector motor control mode, ie. when 99.04 Motor control mode is set to <i>Vector</i> . Notes: <ul style="list-style-type: none"> The start function for the scalar motor control mode is selected by parameter 21.19 Scalar start mode. Starting into a rotating motor is not possible when DC magnetizing is selected (<i>Fast</i> or <i>Const time</i>). With permanent magnet motors, <i>Automatic</i> start mode must be used. This parameter cannot be changed while the drive is running. See also section Start methods – DC magnetization (page 129).	<i>Automatic</i>
	Fast	The drive pre-magnetizes the motor before start. The pre-magnetizing time is determined automatically, being typically 200 ms to 2 s depending on motor size. This mode should be selected if a high break-away torque is required.	0
	Const time	The drive pre-magnetizes the motor before start. The pre-magnetizing time is defined by parameter 21.02 Magnetization time . This mode should be selected if constant pre-magnetizing time is required (for example, if the motor start must be synchronized with the release of a mechanical brake). This setting also guarantees the highest possible break-away torque when the pre-magnetizing time is set long enough.  WARNING! The drive will start after the set magnetizing time has passed even if motor magnetization is not completed. In applications where a full break-away torque is essential, ensure that the constant magnetizing time is long enough to allow generation of full magnetization and torque.	1

	Automatic	Automatic start guarantees optimal motor start in most cases. It includes the flying start function (starting into a rotating motor) and the automatic restart function. The drive motor control program identifies the flux as well as the mechanical state of the motor and starts the motor instantly under all conditions. Note: If parameter <i>99.04 Motor control mode</i> is set to <i>Scalar</i> , no flying start or automatic restart is possible unless parameter <i>21.19 Scalar start mode</i> is set to <i>Automatic</i> .	2										
<i>21.02</i>	<i>Magnetization time</i>	Defines the pre-magnetization time when <ul style="list-style-type: none"> parameter <i>21.01 Start mode</i> is set to <i>Const time</i> (in vector motor control mode), or parameter <i>21.19 Scalar start mode</i> is set to <i>Const time</i> (in scalar motor control mode). After the start command, the drive automatically premagnetizes the motor for the set time. To ensure full magnetizing, set this parameter to the same value as, or higher than, the rotor time constant. 21.22	<i>Start delay</i>	Defines the start delay. After the conditions for start have been fulfilled, the drive waits until the delay has elapsed and then starts the motor. During the delay, warning <i>AFE9 Start delay</i> is shown. Start delay can be used with all start modes.	0.00 s
	0.00...60.00 s	Start delay	1 = 1 s
21.23	<i>Smooth start</i>	Selects the forced current vector rotation mode at low speeds. When the smooth start mode is selected, the rate of acceleration is limited by the acceleration and deceleration ramp times. If the process driven by the permanent magnet synchronous motor has high inertia, slow ramp times are recommended. Can be used for permanent magnet synchronous motors only.	<i>Disabled</i>
	Disabled	Disabled.	0
	Enabled always	Enabled always.	1
	Start only	Enabled when starting the motor.	2
21.24	<i>Smooth start current</i>	Current used in the current vector rotation at low speeds. Increase the smooth start current if the application requires motor shaft swinging needs to be minimized. Note that accurate torque control is not possible in the current vector rotation mode. Can be used for permanent magnet synchronous motors only.	50.0%
	10.0...100.0%	Value in percent of the nominal motor current.	1 = 1%
21.25	<i>Smooth start speed</i>	Output frequency up to which the current vector rotation is used. See parameter <i>21.19 Scalar start mode</i> . Can be used for permanent magnet synchronous motors only.	10.0%
	2.0...100.0%	Value as a percentage of the nominal motor frequency.	1 = 1%
21.26	<i>Torque boost current</i>	Defines the maximum supplied current to motor when (<i>21.19 Scalar start mode</i> is set to <i>Torque boost</i> (see page 393). Parameter value is in percent of the motor nominal current. Nominal value of the parameter is 100.0%. Torque boost is only applied at start, ending when output frequency exceeds 40% of nominal frequency or when output frequency is equal to reference. Can be used in scalar mode only.	100.0%
	15.0...300.0%	Value in percent of the nominal motor current.	1 = 1%
21.30	<i>Speed compensated stop mode</i>	Selects the method used to stop the drive. Speed compensated stop is active only if <ul style="list-style-type: none"> • the operation mode is not torque, and <ul style="list-style-type: none"> • parameter <i>21.03 Stop mode</i> is <i>Ramp</i>. 	<i>Off</i>
	Off	Stop according parameter <i>21.03 Stop mode</i> , no speed compensated stop.	0

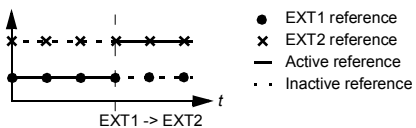

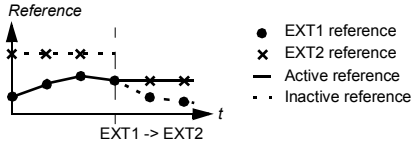

No.	Name/Value	Description	Def/FbEq16
	Speed comp FWD	If the direction of rotation is forward, speed compensation is used for constant distance braking. Speed difference (between used speed and maximum speed) is compensated by running the drive with current speed before the motor is stopped along a ramp. If the direction of rotation is reverse, the drive is stopped along a ramp.	1
	Speed comp REV	If the direction of rotation is reverse, speed compensation is used for constant distance braking. Speed difference (between used speed and maximum speed) is compensated by running the drive with current speed before the motor is stopped along a ramp. If the direction of rotation is forward, the drive is stopped along a ramp.	2
	Speed comp bipolar	Regardless of the direction of rotation, speed compensation is used for constant distance braking. Speed difference (between used speed and maximum speed) is compensated by running the drive with current speed before the motor is stopped along a ramp.	3
21.31	Speed comp stop delay	This delay adds distance to the total distance traveled during a stop from maximum speed. It is used to adjust the distance to match requirements so that the distance traveled is not solely determined by the deceleration rate.	0.00 s
	0.00...1000.00 s	Speed delay.	1 = 1 s
21.32	Speed comp stop threshold	This parameter sets a speed threshold below which the Speed compensated stop feature is disabled. In this speed region, the speed compensated stop is not attempted and the drive stops as it would, using the ramp option.	10%
	0...100%	Speed threshold as a percent of the motor nominal speed.	1 = 1%
21.34	Force auto restart	Forces automatic restart. The parameter is applicable only if parameter 95.04 Control board supply is set to External 24V .	Enable
	Disable	Force auto restart disabled. Parameter 21.18 Auto restart time is in effect if its value is more than 0.0 s.	0
	Enable	Force auto restart enabled. Parameter 21.18 Auto restart time is ignored. The drive never trips on the undervoltage fault and the start signal is on forever. When the DC voltage is restored, the normal operation continues.	1

	Disabled	Floating point control (Motor potentiometer) is disabled and the Floating point control (Motor potentiometer) counter value set to 0.	0
	Enabled (init at stop /power-up)	When enabled, the Floating point control (Motor potentiometer) counter first adopts the value defined by parameter 22.72 Motor potentiometer initial value . The value can then be adjusted from the up and down sources defined by parameters 22.73 Motor potentiometer up source and 22.74 Motor potentiometer down source . A stop or a power cycle will reset the counter to the initial value (22.72).	1

No.	Name/Value	Description	Def/FbEq16
23.12	<i>Acceleration time 1</i>	Defines acceleration time 1 as the time required for the speed to change from zero to the speed defined by parameter 46.01 Speed scaling (not to parameter 30.12 Maximum speed). If the speed reference increases faster than the set acceleration rate, the motor speed will follow the acceleration rate. If the speed reference increases slower than the set acceleration rate, the motor speed will follow the reference. If the acceleration time is set too short, the drive will automatically prolong the acceleration in order not to exceed the drive torque limits.	20.000 s
	0.000...1800.000 s	Acceleration time 1.	10 = 1 s
23.13	<i>Deceleration time 1</i>	Defines deceleration time 1 as the time required for the speed to change from the speed defined by parameter 46.01 Speed scaling (not from parameter 30.12 Maximum speed) to zero. If the speed reference decreases slower than the set deceleration rate, the motor speed will follow the reference. If the reference changes faster than the set deceleration rate, the motor speed will follow the deceleration rate. If the deceleration rate is set too short, the drive will automatically prolong the deceleration in order not to exceed drive torque limits (or not to exceed a safe DC link voltage). If there is any doubt about the deceleration time being too short, ensure that DC overvoltage control is on (parameter 30.30 Overvoltage control). Note: If a short deceleration time is needed for a high inertia application, the drive should be equipped with braking equipment such as a brake chopper and brake resistor.	20.000 s

23.14	<i>Acceleration time 2</i>	Defines acceleration time 2. See parameter 23.12 Acceleration time 1 .	60.000 s

Emergency stop mode and activation source are selected by parameters 21.04 Emergency stop mode and 21.05 Emergency stop source respectively. Emergency stop can also be activated through fieldbus. Notes: <ul style="list-style-type: none">• Emergency stop Off1 uses the standard deceleration ramp as defined by parameters 23.11...23.15.• The same parameter value is also used in frequency control mode (ramp parameters 28.71...28.75).	3.000 s
	0.000...1800.000 s	Emergency stop Off3 deceleration time.	10 = 1 s

23.28	Variable slope enable	<p>Activates the variable slope function, which controls the slope of the speed ramp during a speed reference change. This allows for a constantly variable ramp rate to be generated, instead of just the standard two ramps normally available. If the update interval of the signal from an external control system and the variable slope rate (23.29 Variable slope rate) are equal, speed reference (23.02 Speed ref ramp output) is a straight line.</p>  <p>t = update interval of signal from an external control system A = speed reference change during t</p> <p>This function is only active in external control.</p>	Off

	-10000.00... 10000.00 rpm	Speed reference correction.	See par. 46.01
24.12	<i>Speed error filter time</i>	Defines the time constant of the speed error low-pass filter. If the used speed reference changes rapidly, the possible interferences in the speed measurement can be filtered with the speed error filter. Reducing the ripple with this filter may cause speed controller tuning problems. A long filter time constant and fast acceleration time contradict one another. A very long filter time results in unstable control.	0 ms
	0...10000 ms	Speed error filtering time constant. 0 = filtering disabled.	1 = 1 ms

No.	Name/Value	Description	Def/FbEq16
25.02	<i>Speed proportional gain</i>	<p>Defines the proportional gain (K_p) of the speed controller. Too high a gain may cause speed oscillation. The figure below shows the speed controller output after an error step when the error remains constant.</p>  <p>Gain = $K_p = 1$ T_I = Integration time = 0 T_D = Derivation time = 0</p> <p>Controller output = $K_p \times e$</p> <p>e = Error value</p> <p>If gain is set to 1, a 10% change in error value (reference - actual value) causes the speed controller output to change by 10%, ie. the output value is input \times gain.</p>	10.00
	0.00...250.00	Proportional gain for speed controller.	100 = 1

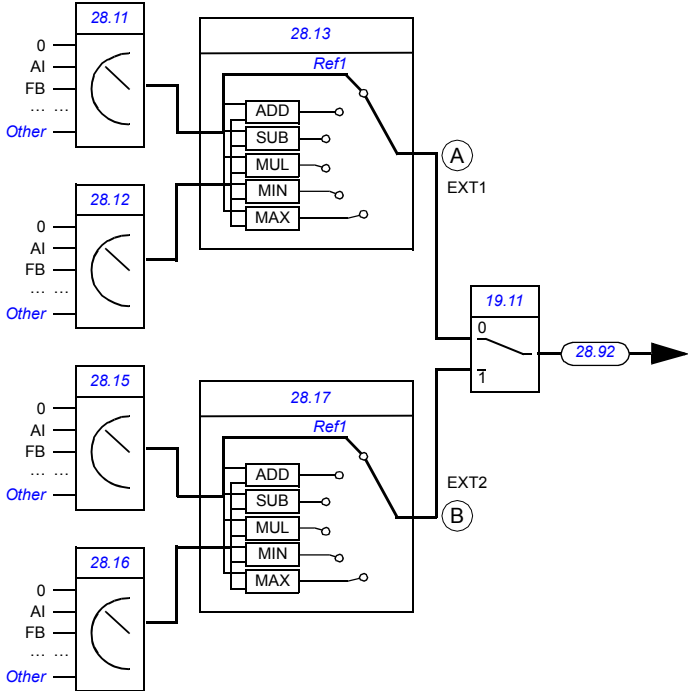

No.	Name/Value	Description	Def/FbEq16
25.03	<i>Speed integration time</i>	<p>Defines the integration time of the speed controller. The integration time defines the rate at which the controller output changes when the error value is constant and the proportional gain of the speed controller is 1. The shorter the integration time, the faster the continuous error value is corrected. This time constant must be set to the same order of magnitude as the time constant (time to respond) of the actual mechanical system being controlled, otherwise instability will result.</p> <p>Setting the integration time to zero disables the I-part of the controller. This is useful to do when tuning the proportional gain; adjust the proportional gain first, then return the integration time.</p> <p>Anti-windup (the integrator just integrates up to 100%) stops the integrator if the controller output is limited.</p> <p>The figure below shows the speed controller output after an error step when the error remains constant.</p>	2.50 s
0.00...1000.00 s		Integration time for speed controller.	10 = 1 s

No.	Name/Value	Description	Def/FbEq16
25.04	<i>Speed derivation time</i>	<p>Defines the derivation time of the speed controller. Derivative action boosts the controller output if the error value changes. The longer the derivation time, the more the speed controller output is boosted during the change. If the derivation time is set to zero, the controller works as a PI controller, otherwise as a PID controller. The derivation makes the control more responsive for disturbances. For simple applications, derivation time is not normally required and should be left at zero.</p> <p>The speed error derivative must be filtered with a low pass filter to eliminate disturbances.</p> <p>The figure below shows the speed controller output after an error step when the error remains constant.</p>  <p>Gain = $K_p = 1$ T_1 = Integration time > 0 T_D = Derivation time > 0 T_s = Sample time period = 250 μs Δe = Error value change between two samples</p>	0.000 s

<i>28.72</i>	<i>Freq acceleration time 1</i>	Defines acceleration time 1 as the time required for the frequency to change from zero to the frequency defined by parameter <i>46.02 Frequency scaling</i> . After this frequency has been reached, the acceleration continues with the same rate to the value defined by parameter <i>30.14 Maximum frequency</i> . If the reference increases faster than the set acceleration rate, the motor will follow the acceleration rate. 30.30	Overvoltage control	Enables the overvoltage control of the intermediate DC link. Fast braking of a high inertia load causes the voltage to rise to the overvoltage control limit. To prevent the DC voltage from exceeding the limit, the overvoltage controller automatically decreases the braking torque. Note: If the drive is equipped with a brake chopper and resistor, or a regenerative supply unit, the controller must be disabled.	Enable

30.31	<i>Undervoltage control</i>	Enables the undervoltage control of the intermediate DC link. If the DC voltage drops due to input power cut off, the undervoltage controller will automatically decrease the motor torque in order to keep the voltage above the lower limit. By decreasing the motor torque, the inertia of the load will cause regeneration back to the drive, keeping the DC link charged and preventing an undervoltage trip until the motor coasts to a stop. This will act as a power-loss ride-through functionality in systems with high inertia, such as a centrifuge or a fan.	<i>Enable</i>

35.55	<i>Motor thermal time constant</i>	<p>Defines the thermal time constant for use with the motor thermal protection model, defined as the time to reach 63% of the nominal motor temperature. See the motor manufacturer's recommendations.</p> <p>For thermal protection according to UL requirements for NEMA class motors, use the rule of thumb: Motor thermal time equals 35 times t_6, where t_6 (in seconds) is specified by the motor manufacturer as the time that the motor can safely operate at six times its rated current.</p> <p>The thermal time for Class 10 trip curve is 350 s, for Class 20 trip curve 700 s and for Class 30 trip curve 1050 s.</p>	256 s
<p>The figure consists of two vertically aligned graphs. The top graph plots 'Motor current' on the y-axis against 'Time' on the x-axis. It shows a rectangular pulse that starts at a certain time, rises to a level marked '100%', remains constant for a duration, and then falls back to zero. The bottom graph plots 'Temperature rise' on the y-axis against 'Time' on the x-axis. It shows a curve that starts at zero, rises asymptotically towards a level marked '100%', and then decays back to zero. A horizontal dashed line at the 63% mark on the y-axis intersects the rising curve. A vertical dashed line drops from the end of the current pulse in the top graph to the x-axis of the bottom graph. A bracket on the x-axis between the start of the pulse and this vertical line is labeled 'Motor thermal time'.</p>

40.14	Set 1 setpoint scaling	<p>Defines, together with parameter 40.15 Set 1 output scaling, a general scaling factor for the process PID control chain.</p> <p>If the parameter is set to zero, automatic setpoint scaling is activated, where suitable setpoint scale is calculated according to selected setpoint source. Actual setpoint scale is shown in parameter 40.61 Setpoint actual scaling.</p> <p>The scaling can be utilized when, for example, the process setpoint is input in Hz, and the output of the PID controller is used as an rpm value in speed control. In this case, this parameter might be set to 50, and parameter 40.15 to the nominal motor speed at 50 Hz.</p> <p>In effect, the output of the PID controller = [40.15] when deviation (setpoint - feedback) = [40.14] and [40.32] = 1.</p> <p>Note: The scaling is based on the ratio between 40.14 and 40.15. For example, the values 50 and 1500 would produce the same scaling as 1 and 30.</p>	0.00

43 Brake chopper		Settings for the internal brake chopper.	
43.01	<i>Braking resistor temperature</i>	Displays the estimated temperature of the brake resistor, or how close the brake resistor is to being too hot. The value is given in percent where 100% is the eventual temperature the resistor would reach when loaded long enough with its rated maximum load capacity (43.09 Brake resistor Pmax cont). The temperature calculation is based on the values of parameters 43.08 , 43.09 and 43.10 , and on the assumption that the resistor is installed as instructed by the manufacturer (ie it cools down as expected). This parameter is read-only.	-
	0.0...120.0%	Estimated brake resistor temperature.	1 = 1%

No.	Name/Value	Description	Def/FbEq16
43.06	<i>Brake chopper function</i>	Enables brake chopper control and selects the brake resistor overload protection method (calculation or measurement). Note: Before enabling brake chopper control, ensure that <ul style="list-style-type: none"> • a brake resistor is connected • overvoltage control is switched off (parameter 30.30 Overvoltage control) • the supply voltage range (parameter 95.01 Supply voltage) has been selected correctly. 	<i>Disabled</i>
	Disabled	Brake chopper control disabled.	0
	Enabled with thermal model	Brake chopper control enabled with brake resistor protection based on the thermal model. If you select this, you must also specify the values needed by the model, ie. parameters 43.08... 43.12 . See the resistor data sheet.	1
	Enabled without thermal model	Brake chopper control enabled without resistor overload protection based on the thermal model. This setting can be used, for example, if the resistor is equipped with a thermal switch that is wired to open the main contactor of the drive if the resistor overheats. For more information, see chapter <i>Resistor braking</i> in the <i>Hardware manual</i> of the drive.	2
	Overvoltage peak protection	Brake chopper control enabled in an overvoltage condition. This setting is intended for situations where <ul style="list-style-type: none"> • the braking chopper is not needed for runtime operation, ie. to dissipate the inertial energy of the motor, • the motor is able to store a considerable amount magnetic energy in its windings, and • the motor might, deliberately or inadvertently, be stopped by coasting. In such a situation, the motor would potentially discharge enough magnetic energy towards the drive to cause damage. To protect the drive, the brake chopper can be used with a small resistor dimensioned merely to handle the magnetic energy (not the inertial energy) of the motor. With this setting, the brake chopper is activated only whenever the DC voltage exceeds the overvoltage limit. During normal use, the brake chopper is not operating.	3
43.07	<i>Brake chopper run enable</i>	Selects the source for quick brake chopper on/off control. 0 = Brake chopper IGBT pulses are cut off 1 = Normal brake chopper IGBT modulation allowed.	<i>On</i>

The value is given in percent of the temperature the resistor reaches when loaded with the power defined by parameter 43.09 Brake resistor Pmax cont .	105%
	0...150%	Brake resistor temperature fault limit.	1 = 1%
43.12	<i>Brake resistor warning limit</i>	Selects the warning limit for the brake resistor protection based on the thermal model. See parameter 43.06 Brake chopper function . When the limit is exceeded, the drive generates warning A793 BR excess temperature . The value is given in percent of the temperature the resistor reaches when loaded with the power defined by parameter 43.09 Brake resistor Pmax cont .	95%

In this case, this parameter might be set to 50, and parameter 74.15 to the nominal motor speed at 50 Hz. In effect, the output of the PID controller [74.15] when deviation (setpoint - feedback) = [74.14] and [74.32] = 1. Note: The scaling is based on the ratio between 74.14 and 74.15 . No.	Name/Value	Description	Def/FbEq16
76.41	<i>Stop point 1</i>	Defines the stop speed (Hz/rpm) for the first auxiliary motor. When the speed of the motor connected directly to the drive falls below this value and one auxiliary motor is running, the stop delay defined by parameter 76.56 Stop delay is started. If the speed is still at the same level or lower when the stop delay elapses, the first auxiliary motor stops. The running speed of the drive is increased by [Start point 1 - Stop point 1] after the auxiliary motor stops.	Vector: 800 rpm; Scalar 25 Hz; 30 Hz (95.20 b0)
	0...32767 rpm/Hz	Speed/frequency	1 = 1 unit

76.59	<i>PFC contactor delay</i>	Start delay for the motor that is directly controlled by the drive. This does not affect the starting of the auxiliary motors.  WARNING! There must always be a delay set if the motors are equipped with star-delta starters. The delay must be set longer than the time setting of the starter. After the motor is switched on by the relay output of the drive, there must be enough time for the star-delta starter to first switch to star and then back to delta before the motor is connected to the drive.	0.50 s

	0.00...1800.00 s	Time.	1 = 1 s

No.	Name/Value	Description	Def/FbEq16
76.61	<i>PFC ramp deceleration time</i>	Defines the deceleration time for the drive motor speed compensation, when an auxiliary motor is started. This ramp time is also used for the drive motor to decelerate after an autochange has occurred. The parameter sets the ramp-up time as seconds from maximum to zero frequency (not from the previous reference to the new reference).	1.00 s
	0.00...1800.00 s	Time.	1 = 1 s
76.70	<i>Autochange</i>	Defines the way the autochange is triggered. In all cases except <i>Even wear</i> , the start order is moved one step forward each time the autochange occurs. If the start order initially is 1-2-3-4, after the first autochange the order will be 2-3-4-1, etc. For <i>Even wear</i> , the start order will be determined so that the running times of all motors remain within the defined limit. 94 LSU control		Control of the supply unit of the drive, such as DC voltage and reactive power reference. Note that the references defined here must also be selected as the reference source in the supply control program to be effective. This group is only visible for ACH580-31. See also section Control of a supply unit (LSU) (page 98).	
94.01	LSU control	Enables/disables the internal INU-LSU state machine. When the state machine is enabled, the inverter unit (INU) controls the supply unit (LSU) and prevents the inverter unit from starting until the supply unit is ready. When the state machine is disabled, the status of the supply unit (LSU) is ignored by the inverter unit.	<i>On</i>

95 HW configuration		Various hardware-related settings.	
95.01	<i>Supply voltage</i>	Selects the supply voltage range. This parameter is used by the drive to determine the nominal voltage of the supply network. The parameter also affects the current ratings and the DC voltage control functions (trip and brake chopper activation limits) of the drive.  WARNING! An incorrect setting may cause the motor to rush uncontrollably, or the brake chopper or resistor to overload. Note: The selections shown depend on the hardware of the drive. If only one voltage range is valid for the drive in question, it is selected by default. Note: In ACH580-31, you have to select the supply voltage manually as the automatic selection is not supported.	<i>Automatic / not selected</i>
	Automatic / not selected	No voltage range selected. The drive will not start modulating before a range is selected, unless parameter 95.02 Adaptive voltage limits is set to <i>Enable</i> , in which case the drive estimates the supply voltage itself. Note: Not supported for ACH580-31.	0

97.03	<i>Slip gain</i>	<p>Defines the slip gain which is used to improve the estimated motor slip. 100% means full slip gain; 0% means no slip gain. The default value is 100%. Other values can be used if a static speed error is detected despite having the setting at full slip gain.</p> <p>Example (with nominal load and nominal slip of 40 rpm): A 1000 rpm constant speed reference is given to the drive. Despite having full slip gain (= 100%), a manual tachometer measurement from the motor axis gives a speed value of 998 rpm. The static speed error is 1000 rpm - 998 rpm = 2 rpm. To compensate the error, the slip gain should be increased to 105% (2 rpm / 40 rpm = 5%).</p>	100%
	0...200%	Slip gain.	1 = 1%
97.04	<i>Voltage reserve</i>	<p>Defines the minimum allowed voltage reserve. When the voltage reserve has decreased to the set value, the drive enters the field weakening area.</p> <p>Note: This is an expert level parameter and should not be adjusted without appropriate skill.</p> <p>If the intermediate circuit DC voltage $U_{dc} = 550 \text{ V}$ and the voltage reserve is 5%, the RMS value of the maximum output voltage in steady-state operation is $0.95 \times 550 \text{ V} / \sqrt{2} = 369 \text{ V}$</p> <p>The dynamic performance of the motor control in the field weakening area can be improved by increasing the voltage reserve value, but the drive enters the field weakening area earlier.</p>	-2%
	-4...50%	Voltage reserve.	1 = 1%
97.05	<i>Flux braking</i>	<p>Defines the level of flux braking power. (Other stopping and braking modes can be configured in parameter group 21 Start/stop mode).</p> <p>Note: This is an expert level parameter and should not be adjusted without appropriate skill.</p>	<i>Disabled</i>
	Disabled	Flux braking is disabled.	0
	Moderate	Flux level is limited during the braking. Deceleration time is longer compared to full braking.	1
	Full	<p>Maximum braking power. Almost all available current is used to convert the mechanical braking energy to thermal energy in the motor.</p> <p> WARNING! Using full flux braking heats up the motor especially in cyclic operation. Make sure that the motor can withstand this if you have a cyclic application.</p>	2
97.08	<i>Optimizer minimum torque</i>	<p>This parameter can be used to improve the control dynamics of a synchronous reluctance motor or a salient permanent magnet synchronous motor.</p> <p>As a rule of thumb, define a level to which the output torque must rise with minimum delay. 97.10	<i>Signal injection</i>	<p>Enables the anti-cogging function: a high-frequency alternating signal is injected to the motor in the low speed region to improve the stability of torque control. This removes the "cogging" that can sometimes be seen as the rotor passes the motor magnetic poles. Anti-cogging can be enabled with different amplitude levels.</p> <p>Notes:</p> <ul style="list-style-type: none"> • This is an expert level parameter and should not be adjusted without appropriate skill. • Use as low a level as possible that gives satisfactory performance. • Signal injection cannot be applied to asynchronous motors. 	<i>Disabled</i>

	Enabled (20%)	Anti-cogging enabled with amplitude level of 20%.	4
97.11	<i>TR tuning</i>	<p>Rotor time constant tuning.</p> <p>This parameter can be used to improve torque accuracy in closed-loop control of an induction motor. 	Permanent magnet motor	Permanent magnet motor. Three-phase AC synchronous motor with permanent magnet rotor and sinusoidal BackEMF voltage. Note: With permanent magnet motors special attention must be paid on setting the motor nominal values correctly in parameter group 99 Motor data . You must use vector control. If the nominal BackEMF voltage of the motor is not available, a full ID run should be performed for improving performance.	1
	SynRM	Synchronous reluctance motor. Three-phase AC synchronous motor with salient pole rotor without permanent magnets. With synchronous reluctance motors you must use vector control.	2
99.04	<i>Motor control mode</i>	Selects the motor control mode.	<i>Scalar</i>

See parameter 99.13 ID run requested . Note: In vector control the drive performs a standstill ID run at the first start if ID run has not been previously performed. A new start command is required after standstill ID run. Note: To achieve a better motor control performance, you can perform a normal ID run without load. See also section <i>Operating modes of the drive</i> (page 97)).	0

No.	Name/Value	Description	Def/FbEq16
	Scalar	Scalar control. Suitable for most applications, if top performance is not required. Motor identification run is not required. Note: Scalar control must be used in the following situations: <ul style="list-style-type: none"> • with multimotor systems 1) if the load is not equally shared between the motors, 2) if the motors are of different sizes, or 3) if the motors are going to be changed after the motor identification (ID run) • if the nominal current of the motor is less than 1/6 of the nominal output current of the drive • if the drive is used with no motor connected (for example, for test purposes). Note: Correct motor operation requires that the magnetizing current of the motor does not exceed 90% of the nominal current of the inverter. See also section Operating modes of the drive (page 91).	1

99.07	Motor nominal voltage	Defines the nominal motor voltage supplied to the motor. This setting must match the value on the rating plate of the motor. Notes: <ul style="list-style-type: none"> • With permanent magnet motors, the nominal voltage is the BackEMF voltage at nominal speed of the motor. If the voltage is given as voltage per rpm, for example, 60 V per 1000 rpm, the voltage for a nominal speed of 3000 rpm is $3 \times 60 \text{ V} = 180 \text{ V}$. • The stress on the motor insulation is always dependent on the drive supply voltage. This also applies to the case where the motor voltage rating is lower than that of the drive and the supply. • This parameter cannot be changed while the drive is running. 	0.0 V

99.13	<i>ID run requested</i>	<p>Selects the type of the motor identification routine (ID run) performed at the next start of the drive. During the ID run, the drive will identify the characteristics of the motor for optimum motor control.</p> <p>If no ID run has been performed yet (or if default parameter values have been restored using parameter 96.06 Parameter restore), this parameter is automatically set to <i>Standstill</i>, signifying that an ID run must be performed.</p> <p>After the ID run, the drive stops and this parameter is automatically set to <i>None</i>.</p> <p>Notes:</p> <ul style="list-style-type: none"> • To ensure that the ID run can work properly, the drive limits in group 30 (maximum speed and minimum speed, and maximum torque and minimum torque) must be large enough (the range specified by the limits must be wide enough. If, for example, speed limits are less than the motor nominal speed, the ID run cannot be completed. • For the <i>Advanced</i> ID run, the machinery must always be de-coupled from the motor. • With a permanent magnet or synchronous reluctance motor, a <i>Normal</i>, <i>Reduced</i> or <i>Standstill</i> ID run requires that the motor shaft is NOT locked and the load torque is less than 10%. • With scalar control mode (99.04 Motor control mode = Scalar), the ID run is not requested automatically. However, an ID run can be performed for more accurate torque estimation. • Once the ID run is activated, it can be canceled by stopping the drive. • The ID run must be performed every time any of the motor parameters (99.04, 99.06...99.12) have been changed. • Ensure that the Safe Torque Off and emergency stop circuits (if any) are closed during the ID run. • Mechanical brake (if present) is not opened by the logic for the ID run. • This parameter cannot be changed while the drive is running. 	<i>None</i>

	Normal	<p>Normal ID run. Guarantees good control accuracy for all cases. The ID run takes about 90 seconds. This mode should be selected whenever it is possible.</p> <p>Notes:</p> <ul style="list-style-type: none"> • If the load torque will be higher than 20% of motor nominal torque, or if the machinery is not able to withstand the nominal torque transient during the ID run, then the driven machinery must be de-coupled from the motor during a Normal ID run. • Check the direction of rotation of the motor before starting the ID run. During the run, the motor will rotate in the forward direction. <p> WARNING! The motor will run at up to approximately 50...100% of the nominal speed during the ID run. Reduced ID run is completed faster than the Normal ID Run (< 90 seconds).</p> <p>Note: Check the direction of rotation of the motor before starting the ID run. 	Reserved		4...5
	Advanced	<p>Advanced ID run. Only for frames R6...R11 and ACH580-31. Guarantees the best possible control accuracy. The ID run takes a very long time to complete. This mode should be selected when top performance is needed across the whole operating area.</p> <p>Note: The driven machinery must be de-coupled from the motor because of high torque and speed transients that are applied.</p> <p> WARNING! The motor may run at up to the maximum (positive) and minimum (negative) allowed speed during the ID run. Several accelerations and decelerations are done. The maximum torque, current and speed allowed by the limit parameters may be utilized. ENSURE THAT IT IS SAFE TO RUN THE MOTOR BEFORE PERFORMING THE ID RUN!</p>	6

99.16	<i>Motor phase order</i>	Switches the rotation direction of motor. This parameter can be used if the motor turns in the wrong direction (for example, because of the wrong phase order in the motor cable), and correcting the cabling is considered impractical. Differences in the default values between 50 Hz and 60 Hz supply frequency settings

Parameter [95.20 HW options word 1 bit 0 Supply frequency 60 Hz](#) changes the drive parameter default values according to the supply frequency, 50 Hz or 60 Hz. The bit is set according to the market before the drive is delivered.

If you need to change from 50 Hz to 60 Hz, or vice versa, change the value of the bit and then do a complete reset to the drive. After that you have to reselect the macro to be used.

The table below shows the parameters whose default values depend on the supply frequency setting. The supply frequency setting, with the type designation of the drive, also affects Group [99 Motor data](#) parameter values though these parameters are not listed in the table.
